## Volvo 142E
                        21.4
                               4 121.0 109 4.11 2.780 18.60
```

We will be interested in three of the variables: mpg, hp, and am.

- mpg: fuel efficiency, in miles per gallon.
- hp: horsepower, in foot-pounds per second.
- am: transmission. Automatic or manual.

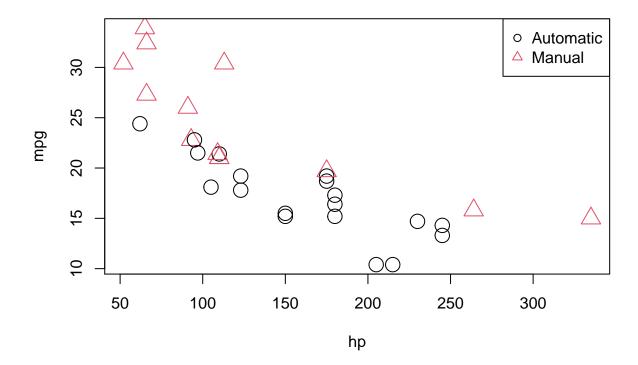

As we often do, we will start by plotting the data. We are interested in mpg as the response variable, and hp as a predictor.

```
plot(mpg ~ hp, data = mtcars, cex = 2)
```

Since we are also interested in the transmission type, we could also label the points accordingly.

```
plot(mpg ~ hp, data = mtcars, col = am + 1, pch = am + 1, cex = 2)
legend("topright", c("Automatic", "Manual"), col = c(1, 2), pch = c(1, 2))
```

We used a common R "trick" when plotting this data. The am variable takes two possible values; 0 for automatic transmission, and 1 for manual transmissions. R can use numbers to represent colors, however the color for 0 is white. So we take the am vector and add 1 to it. Then observations with automatic transmissions are now represented by 1, which is black in R, and manual transmission are represented by 2, which is red in R. (Note, we are only adding 1 inside the call to plot(), we are not actually modifying the values stored in am.)

We now fit the SLR model

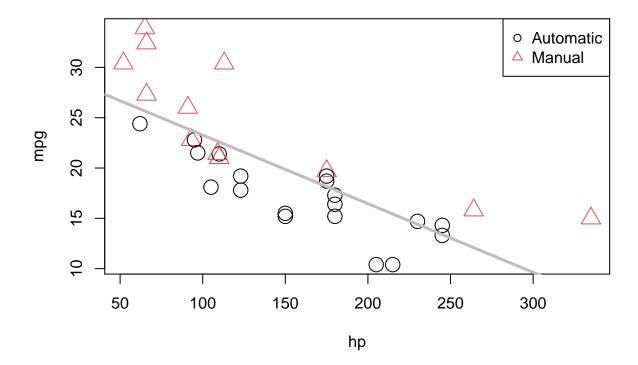

$$Y = \beta_0 + \beta_1 X_1 + \epsilon,$$

where Y is mpg and X_1 is hp. For notational brevity, we drop the index i for observations.

```
mpg_hp_slr = lm(mpg ~ hp, data = mtcars)
```

We then re-plot the data and add the fitted line to the plot.

```
plot(mpg ~ hp, data = mtcars, col = am + 1, pch = am + 1, cex = 2)
abline(mpg_hp_slr, lwd = 3, col = "grey")
legend("topright", c("Automatic", "Manual"), col = c(1, 2), pch = c(1, 2))
```

We should notice a pattern here. The red, manual observations largely fall above the line, while the black, automatic observations are mostly below the line. This means our model underestimates the fuel efficiency of manual transmissions, and overestimates the fuel efficiency of automatic transmissions. To correct for this, we will add a predictor to our model, namely, am as X_2 .

Our new model is

$$Y = \beta_0 + \beta_1 X_1 + \beta_2 X_2 + \epsilon,$$

where X_1 and Y remain the same, but now

$$X_2 = \begin{cases} 1 & \text{manual transmission} \\ 0 & \text{automatic transmission} \end{cases}.$$

First, note that am is already a dummy variable, since it uses the values 0 and 1 to represent automatic and manual transmissions. Often, a variable like am would store the character values auto and man and we would either have to convert these to 0 and 1, or, as we will see later, R will take care of creating dummy variables for us

So, to fit the above model, we do so like any other multiple regression model we have seen before.

Briefly checking the output, we see that R has estimated the three β parameters.

```
##
## Call:
## lm(formula = mpg ~ hp + am, data = mtcars)
##
## Coefficients:
   (Intercept)
##
                          hp
                                         am
      26.58491
                    -0.05889
##
                                   5.27709
```

Since X_2 can only take values 0 and 1, we can effectively write two different models, one for manual and one for automatic transmissions.

For automatic transmissions, that is $X_2 = 0$, we have,

$$Y = \beta_0 + \beta_1 X_1 + \epsilon.$$

Then for manual transmissions, that is $X_2 = 1$, we have,

$$Y = (\beta_0 + \beta_2) + \beta_1 X_1 + \epsilon.$$

Notice that these models share the same slope, β_1 , but have different intercepts, differing by β_2 . So the change in mpg is the same for both models, but on average mpg differs by β_2 between the two transmission

We'll now calculate the estimated slope and intercept of these two models so that we can add them to a plot. Note that:

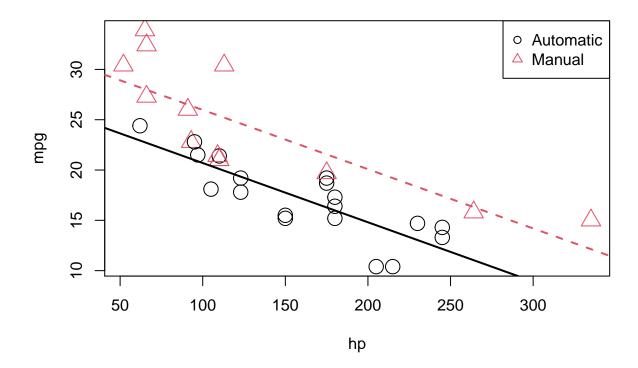

- $\hat{\beta}_0 = \text{coef(mpg_hp_add)[1]} = 26.5849137$ $\hat{\beta}_1 = \text{coef(mpg_hp_add)[2]} = -0.0588878$ $\hat{\beta}_2 = \text{coef(mpg_hp_add)[3]} = 5.2770853$

We can then combine these to calculate the estimated slope and intercepts.

```
int auto = coef(mpg hp add)[1]
int_manu = coef(mpg_hp_add)[1] + coef(mpg_hp_add)[3]
slope_auto = coef(mpg_hp_add)[2]
slope_manu = coef(mpg_hp_add)[2]
```

Re-plotting the data, we use these slopes and intercepts to add the "two" fitted models to the plot.

```
plot(mpg ~ hp, data = mtcars, col = am + 1, pch = am + 1, cex = 2)
abline(int_auto, slope_auto, col = 1, lty = 1, lwd = 2) # add line for auto
abline(int_manu, slope_manu, col = 2, lty = 2, lwd = 2) # add line for manual
legend("topright", c("Automatic", "Manual"), col = c(1, 2), pch = c(1, 2))
```

We notice right away that the points are no longer systematically incorrect. The red, manual observations vary about the red line in no particular pattern without underestimating the observations as before. The black, automatic points vary about the black line, also without an obvious pattern.

They say a picture is worth a thousand words, but as a statistician, sometimes a picture is worth an entire analysis. The above picture makes it plainly obvious that β_2 is significant, but let's verify mathematically. Essentially we would like to test:

$$H_0: \beta_2 = 0 \text{ vs } H_1: \beta_2 \neq 0.$$

This is nothing new. Again, the math is the same as the multiple regression analyses we have seen before. We could perform either a t or F test here. The only difference is a slight change in interpretation. We could think of this as testing a model with a single line (H_0) against a model that allows two lines (H_1) .

To obtain the test statistic and p-value for the t-test, we would use

```
summary(mpg_hp_add)$coefficients["am",]

## Estimate Std. Error t value Pr(>|t|)
## 5.277085e+00 1.079541e+00 4.888270e+00 3.460318e-05
```

To do the same for the F test, we would use

```
anova(mpg_hp_slr, mpg_hp_add)

## Analysis of Variance Table
```

```
## ## Model 1: mpg ~ hp ## Model 2: mpg ~ hp + am
```

```
## Res.Df RSS Df Sum of Sq F Pr(>F)
## 1  30 447.67
## 2  29 245.44 1  202.24 23.895 3.46e-05 ***
## ---
## Signif. codes: 0 '***' 0.001 '**' 0.05 '.' 0.1 ' ' 1
```

Notice that these are indeed testing the same thing, as the p-values are exactly equal. (And the F test statistic is the t test statistic squared.)

Recapping some interpretations:

- $\hat{\beta}_0 = 26.5849137$ is the estimated average mpg for a car with an automatic transmission and **0** hp.
- $\hat{\beta}_0 + \hat{\beta}_2 = 31.8619991$ is the estimated average mpg for a car with a manual transmission and **0** hp.
- $\hat{\beta}_2 = 5.2770853$ is the estimated **difference** in average mpg for cars with manual transmissions as compared to those with automatic transmission, for any hp.
- $\hat{\beta}_1 = -0.0588878$ is the estimated change in average mpg for an increase in one hp, for either transmission types.

Interactions

To remove the "same slope" restriction, we will now discuss **interaction**. To illustrate this concept, we will return to the autompg dataset we created in the last chapter, with a few more modifications.

```
# read data frame from the web
autompg = read.table(
  "http://archive.ics.uci.edu/ml/machine-learning-databases/auto-mpg/auto-mpg.data",
 quote = "\"",
  comment.char = "",
 stringsAsFactors = FALSE)
# give the dataframe headers
colnames(autompg) = c("mpg", "cyl", "disp", "hp", "wt", "acc", "year", "origin", "name")
# remove missing data, which is stored as "?"
autompg = subset(autompg, autompg$hp != "?")
# remove the plymouth reliant, as it causes some issues
autompg = subset(autompg, autompg$name != "plymouth reliant")
# give the dataset row names, based on the engine, year and name
rownames(autompg) = paste(autompg$cyl, "cylinder", autompg$year, autompg$name)
# remove the variable for name
autompg = subset(autompg, select = c("mpg", "cyl", "disp", "hp", "wt", "acc", "year", "origin"))
# change horsepower from character to numeric
autompg$hp = as.numeric(autompg$hp)
# create a dummary variable for foreign vs domestic cars. domestic = 1.
autompg$domestic = as.numeric(autompg$origin == 1)
# remove 3 and 5 cylinder cars (which are very rare.)
autompg = autompg[autompg$cyl != 5,]
autompg = autompg[autompg$cyl != 3,]
# the following line would verify the remaining cylinder possibilities are 4, 6, 8
#unique(autompg$cyl)
# change cyl to a factor variable
autompg$cyl = as.factor(autompg$cyl)
str(autompg)
```

```

```

We've removed cars with 3 and 5 cylinders, as well as created a new variable domestic which indicates whether or not a car was built in the United States. Removing the 3 and 5 cylinders is simply for ease of demonstration later. The new variable domestic takes the value 1 if the car was built in the United States, and 0 otherwise, which we will refer to as "foreign." (We are arbitrarily using the United States as the reference point here.) We have also made cyl and origin into factor variables, which we will discuss later.

We'll now be concerned with three variables: mpg, disp, and domestic. We will use mpg as the response. We can fit a model,

$$Y = \beta_0 + \beta_1 X_1 + \beta_2 X_2 + \epsilon,$$

where

- Y is mpg, the fuel efficiency in miles per gallon,
- X_1 is disp, the displacement in cubic inches,
- X_2 is domestic as described above, which is a dummy variable.

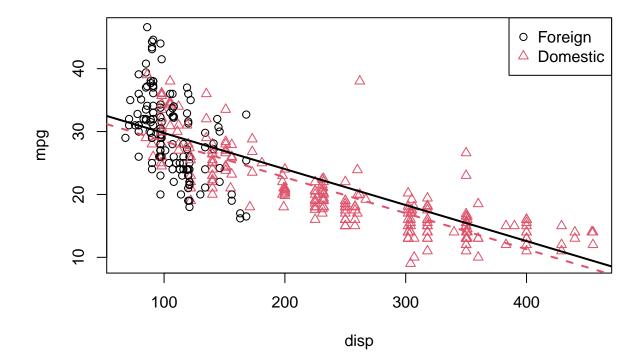

$$X_2 = \begin{cases} 1 & \text{Domestic} \\ 0 & \text{Foreign} \end{cases}$$

We will fit this model, extract the slope and intercept for the "two lines," plot the data and add the lines.

```
mpg_disp_add = lm(mpg ~ disp + domestic, data = autompg)
int_for = coef(mpg_disp_add)[1]
int_dom = coef(mpg_disp_add)[1] + coef(mpg_disp_add)[3]

slope_for = coef(mpg_disp_add)[2]
slope_dom = coef(mpg_disp_add)[2]

plot(mpg ~ disp, data = autompg, col = domestic + 1, pch = domestic + 1)
abline(int_for, slope_for, col = 1, lty = 1, lwd = 2) # add line for foreign cars
abline(int_dom, slope_dom, col = 2, lty = 2, lwd = 2) # add line for domestic cars
legend("topright", c("Foreign", "Domestic"), pch = c(1, 2), col = c(1, 2))
```

This is a model that allows for two *parallel* lines, meaning the mpg can be different on average between foreign and domestic cars of the same engine displacement, but the change in average mpg for an increase in displacement is the same for both. We can see this model isn't doing very well here. The red line fits the red points fairly well, but the black line isn't doing very well for the black points, it should clearly have a more negative slope. Essentially, we would like a model that allows for two different slopes.

Consider the following model,

$$Y = \beta_0 + \beta_1 X_1 + \beta_2 X_2 + \beta_3 X_1 X_2 + \epsilon,$$

where X_1 , X_2 , and Y are the same as before, but we have added a new **interaction** term X_1X_2 which multiplies X_1 and X_2 , so we also have an additional β parameter β_3 .

This model essentially creates two slopes and two intercepts, β_2 being the difference in intercepts and β_3 being the difference in slopes. To see this, we will break down the model into the two "sub-models" for foreign and domestic cars.

For foreign cars, that is $X_2 = 0$, we have

$$Y = \beta_0 + \beta_1 X_1 + \epsilon.$$

For domestic cars, that is $X_2 = 1$, we have

$$Y = (\beta_0 + \beta_2) + (\beta_1 + \beta_3)X_1 + \epsilon.$$

These two models have both different slopes and intercepts.

- β_0 is the average mpg for a foreign car with **0** disp.
- β_1 is the change in average mpg for an increase of one disp, for foreign cars.
- $\beta_0 + \beta_2$ is the average mpg for a domestic car with **0** disp.
- $\beta_1 + \beta_3$ is the change in average mpg for an increase of one disp, for domestic cars.

How do we fit this model in R? There are a number of ways.

One method would be to simply create a new variable, then fit a model like any other.

```
autompg$x3 = autompg$disp * autompg$domestic # THIS CODE NOT RUN!
do_not_do_this = lm(mpg ~ disp + domestic + x3, data = autompg) # THIS CODE NOT RUN!
```

You should only do this as a last resort. We greatly prefer not to have to modify our data simply to fit a model. Instead, we can tell R we would like to use the existing data with an interaction term, which it will create automatically when we use the : operator.

```
mpg_disp_int = lm(mpg ~ disp + domestic + disp:domestic, data = autompg)
```

An alternative method, which will fit the exact same model as above would be to use the * operator. This method automatically creates the interaction term, as well as any "lower order terms," which in this case are the first order terms for disp and domestic

```
mpg_disp_int2 = lm(mpg ~ disp * domestic, data = autompg)
```

We can quickly verify that these are doing the same thing.

```
coef(mpg_disp_int)
```

```
## (Intercept) disp domestic disp:domestic
## 46.0548423 -0.1569239 -12.5754714 0.1025184
coef(mpg_disp_int2)
```

```
## (Intercept) disp domestic disp:domestic
## 46.0548423 -0.1569239 -12.5754714 0.1025184
```

We see that both the variables, and their coefficient estimates are indeed the same for both models.

```

```

We see that using summary() gives the usual output for a multiple regression model. We pay close attention to the row for disp:domestic which tests,

$$H_0: \beta_3 = 0.$$

In this case, testing for $\beta_3 = 0$ is testing for two lines with parallel slopes versus two lines with possibly different slopes. The disp:domestic line in the summary() output uses a t-test to perform the test.

We could also use an ANOVA F-test. The additive model, without interaction is our null model, and the interaction model is the alternative.

```
anova(mpg_disp_add, mpg_disp_int)
```

```
## Analysis of Variance Table
##
## Model 1: mpg ~ disp + domestic
## Model 2: mpg ~ disp + domestic + disp:domestic
## Res.Df RSS Df Sum of Sq F Pr(>F)
## 1 380 7714.0
## 2 379 7032.6 1 681.36 36.719 3.294e-09 ***
## ---
## Signif. codes: 0 '***' 0.001 '**' 0.05 '.' 0.1 ' ' 1
```

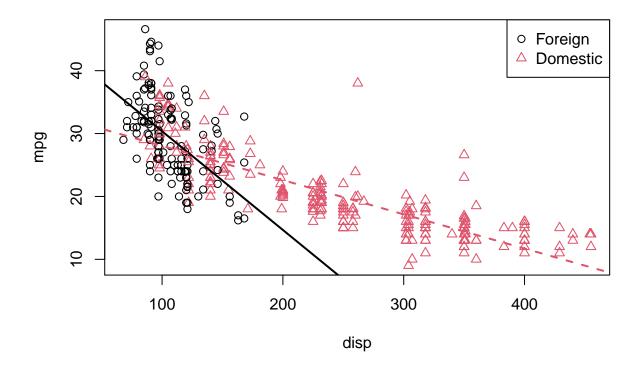

Again we see this test has the same p-value as the t-test. Also the p-value is extremely low, so between the two, we choose the interaction model.

```
int_for = coef(mpg_disp_int)[1]
int_dom = coef(mpg_disp_int)[1] + coef(mpg_disp_int)[3]

slope_for = coef(mpg_disp_int)[2]
slope_dom = coef(mpg_disp_int)[2] + coef(mpg_disp_int)[4]
```

Here we again calculate the slope and intercepts for the two lines for use in plotting.

```
plot(mpg ~ disp, data = autompg, col = domestic + 1, pch = domestic + 1)
abline(int_for, slope_for, col = 1, lty = 1, lwd = 2) # line for foreign cars
abline(int_dom, slope_dom, col = 2, lty = 2, lwd = 2) # line for domestic cars
legend("topright", c("Foreign", "Domestic"), pch = c(1, 2), col = c(1, 2))
```

We see that these lines fit the data much better, which matches the result of our tests.

So far we have only seen interaction between a categorical variable (domestic) and a numerical variable (disp). While this is easy to visualize, since it allows for different slopes for two lines, it is not the only type of interaction we can use in a model. We can also consider interactions between two numerical variables.
